## Activation, Metabolism and Perfusion of the Heart: Simulation and experimental models (Developments in Cardiovascular Medicine)

The basic mechanism underlying directional differences in excitability, conduction velocity, and safety factor that lead to circus movement reentry in cardiac muscle is generally attributed to a spatial difference in the refractory period as originally described by Mines [1] or to a depressed segment as described by Schmitt and Erlanger [2]. A departure from this depolarization in cardiac muscle involve quantities, such as  $V_{max}$  that are not directly descriptive of the underlying mechanisms of propagation.
